

Cloud Intelligence Dashboards – AWS Config Dashboard

Shift-Left Compliance Practices and Empower Resource Management on AWS

The [AWS Config Resource Compliance Dashboard](#) provides a centralized "single pane of glass" for tracking AWS resource inventory and compliance status across multiple AWS accounts and regions using AWS Config data. Through this unified platform, organizations can bridge the gap between security oversight and operational execution, creating more efficient and secure cloud infrastructure management and compliance processes.

DEMOCRATIZE COMPLIANCE VISIBILITY

The dashboard offers visibility over AWS resources and security compliance to field teams, without granting access to dedicated security tooling accounts or the AWS Config service console. Leverage Amazon QuickSight's row-level security to restrict field teams' visibility to their own data securely.

SHIFT-LEFT SECURITY AND COMPLIANCE PRACTICES

Organizations can establish a continuous compliance review process, shift-left their compliance practices and create a short feedback loop from security to field teams to keep non-compliant resources to a minimum. Track compliance of AWS Config rules and conformance packs per service, region, and account; identify resources that require compliance remediation. Verify that your tagging strategy is consistently applied across accounts and regions. Find which resources were recently created, updated or deleted by browsing the timeline of your configuration events. During audit reviews, show AWS resource metadata and demonstrate that your critical resources were not tampered with. Visualize the timestamps of the last successful AWS Config data import and confirm that you are receiving data from all accounts and regions.

A SIMPLIFIED CONFIGURATION MANAGEMENT DATABASE (CMDB) EXPERIENCE IN AWS

Avoid investment in a dedicated external CMDB system or third-party tools. Access the inventory of resources in a single pane of glass, filter resources by account, region, and fields that are specific to the resource, such as IP address. If you tag your resources—for example, to map them to the application, owning team, and environment—specify those tags to the dashboard and they will be displayed alongside the other resource-specific information, and used for filtering your configuration items.
